## Preliminaries

### 1.1 Givental formalism (Patrick, Feb 01)

**1.1.1 Introduction** Let  $X$  be a smooth projective variety. Then for any  $g, n \in \mathbb{Z}_{\geq 0}, \beta \in H_2(X, \mathbb{Z})$ , there exists a moduli space  $\overline{\mathcal{M}}_{g,n}(X, \beta)$  (Givental's notation is  $X_{g,n,\beta}$ ) of *stable maps*  $f: C \rightarrow X$  from genus- $g$ ,  $n$ -marked prestable curves to  $X$  with  $f_*[C] = \beta$ . It is well-known that  $\overline{\mathcal{M}}_{g,n}(X, \beta)$  has a virtual fundamental class

$$[\overline{\mathcal{M}}_{g,n}(X, \beta)]^{\text{vir}} \in A_\delta(\overline{\mathcal{M}}_{g,n}(X, \beta)), \quad \delta = \int_\beta c_1(X) + (\dim X - 3)(1 - g) + 3.$$

In addition, there is a universal curve and sections

$$\mathcal{C} \xrightleftharpoons[\sigma_i]{\pi} \overline{\mathcal{M}}_{g,n}(X, \beta).$$

In this setup, there are tautological classes

$$\psi_i := c_1(\sigma_i^* \omega_\pi) \in H^2(\overline{\mathcal{M}}_{g,n}(X, \beta)).$$

This allows us to define individual Gromov-Witten invariants by

$$\langle \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n,\beta}^X = \int_{[\overline{\mathcal{M}}_{g,n}(X, \beta)]^{\text{vir}}} \prod_{i=1}^n \text{ev}_i^* \phi_i \cdot \psi_i^{a_i}.$$

These invariants satisfy various relations. The first is the *string equation*:

$$\langle \tau_0(1) \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n+1,\beta}^X = \sum_{i=1}^n \left\langle \tau_{a_i-1}(\phi_i) \prod_{j \neq i} \tau_{a_j}(\phi_j) \right\rangle_{g,n,\beta}^X.$$

The next is the *dilaton equation*:

$$\langle \tau_1(1) \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n+1,\beta}^X = (2g - 2 + n) \langle \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n,\beta}^X.$$

Finally, we have the *divisor equation* when one insertion is a divisor  $D \in H^2(X)$ :

$$\begin{aligned} \langle \tau_0(D) \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n+1,\beta}^X &= \left( \int_{\beta} D \right) \cdot \langle \tau_{a_1}(\phi_1) \cdots \tau_{a_n}(\phi_n) \rangle_{g,n,\beta}^X \\ &\quad + \sum_{i=1}^n \left\langle \tau_{a_i-1}(\phi_i \cdot D) \prod_{j \neq i} \tau_{a_j}(\phi_j) \right\rangle_{g,n,\beta}^X. \end{aligned}$$

It is often useful to package Gromov-Witten invariants into various generating series.

**Definition 1.1.1.** The *quantum cohomology*  $QH^*(X)$  of  $X$  is defined by the formula

$$(a \star_t b, c) := \sum_{\beta, n} \frac{Q^\beta}{n!} \langle a, b, c, t, \dots, t \rangle_{0,3+n,\beta}^X$$

for any  $t \in H^*(X)$ . This is a commutative and associative product.

The *small quantum cohomology* is obtained by setting  $t = 0$  and the ordinary cohomology is obtained by further setting  $Q = 0$ .

*Remark 1.1.2.* Convergence of the formula does not hold in general, so quantum cohomology needs to be treated as a formal object.

**Definition 1.1.3.** Let  $\phi_i$  be a basis of  $H^*(X)$  and  $\phi^i$  be the dual basis. Then the *J-function* of  $X$  is the cohomology-valued function

$$J_X(t, z) := z + t + \sum_i \sum_{n,\beta} \frac{Q^\beta}{n!} \left\langle \frac{\phi_i}{z - \psi}, t, \dots, t \right\rangle_{0,n+1,\beta}^X \phi^i.$$

**Definition 1.1.4.** The *genus-0 GW potential* of  $X$  is the (formal) function

$$\mathcal{F}^X(t(z)) = \sum_{\beta, n} \frac{Q^\beta}{n!} \langle t(\psi), \dots, t(\psi) \rangle_{0,n,\beta}^X.$$

The associativity of the quantum product is equivalent to the PDE

$$\sum_{e,f} \mathcal{F}_{abe}^X \eta^{ef} \mathcal{F}_{cdf} = \sum_{e,f} \mathcal{F}_{ade}^X \eta^{ef} \mathcal{F}_{bcf}^X$$

for any  $a, b, c, d$ , which are known as the *WDVV equations*. Here, we choose coordinates on  $H^*(X)$  and set  $z = 0$  (only consider primary insertions). In addition, set  $\eta_{ef}$  to be the components of the Poincaré pairing and let  $\eta^{ef}$  be the inverse matrix.

**1.1.2 Frobenius manifolds** A Frobenius manifold can be thought of as a formalization of the WDVV equations.

**Definition 1.1.5.** A *Frobenius manifold* is a complex manifold  $M$  with a flat symmetric bilinear form  $\langle -, - \rangle$  (meaning that the Levi-Civita connection has zero curvature) on  $TM$  and a holomorphic system of (commutative, associative) products  $\star_t$  on  $T_t M$  satisfying:

1. The unit vector field  $\mathbf{1}$  is flat:  $\nabla \mathbf{1} = 0$ ;

2. For any  $t$  and  $a, b, c \in T_t M$ ,  $\langle a \star_t b, c \rangle = \langle a, b \star_t c \rangle$ ;
3. If  $c(u, v, w) := \langle u \star_t v, w \rangle$ , then the tensor  $(\nabla_z c)(u, v, w)$  is symmetric in  $u, v, w, z \in T_t M$ .

If there exists a vector field  $E$  such that  $\nabla \nabla E = 0$  and complex number  $d$  such that:

1.  $\nabla \nabla E = 0$ ;
2.  $\mathcal{L}_E(u \star v) - \mathcal{L}_E u \star v - u \star \mathcal{L}_E v = u \star v$  for all vector fields  $u, v$ ;
3.  $\mathcal{L}_E \langle u, v \rangle - \langle \mathcal{L}_E u, v \rangle - \langle u, \mathcal{L}_E v \rangle = (2 - d) \langle u, v \rangle$  for all vector fields  $u, v$ ,

then  $E$  is called an *Euler vector field* and the Frobenius manifold  $M$  is called *conformal*.

**Example 1.1.6.** Let  $X$  be a smooth projective variety. Then we can give  $H^*(X)$  the structure of a Frobenius algebra with the Poincaré pairing and the quantum product. Note that the quantum product does not converge in general, so we must treat this as a formal object. The Euler vector field is given by

$$E_X = c_1(X) + \sum_i \left(1 - \frac{\deg \phi_i}{2}\right) t^i \phi_i,$$

where a general element of  $H^*(X)$  is given by  $t = \sum_i t^i \phi_i$ . We will also impose that  $\phi_1 = \mathbf{1}$ . There is another very important structure, the *quantum connection*, which is given by the formula

$$\begin{aligned} \nabla_{t^i} &:= \partial_{t^i} + \frac{1}{z} \phi_i \star_t \\ \nabla_{z \frac{d}{dz}} &:= z \frac{d}{dz} - \frac{1}{z} E_X \star_t + \mu_X. \end{aligned}$$

Here,  $\mu_X$  is the *grading operator*, defined for pure degree classes  $\phi \in H^*(X)$  by

$$\mu_X(\phi) = \frac{\deg \phi - \dim X}{2} \phi.$$

Finally, in the direction of the Novikov variables, we have

$$\nabla_{\zeta Q \partial_Q} = \zeta Q \partial_Q + \frac{1}{z} \zeta \star_t.$$

*Remark 1.1.7.* For a general conformal Frobenius manifold  $(H, (-, -), \star, E)$ , there is still a *deformed flat connection* or *Dubrovin connection* given by

$$\begin{aligned} \nabla_{t^i} &:= \frac{\partial}{\partial t^i} + \frac{1}{z} \phi_i \star \\ \nabla_{z \frac{d}{dz}} &:= z \frac{d}{dz} - \frac{1}{z} E \star. \end{aligned}$$

**Definition 1.1.8.** The *quantum D-module* of  $X$  is the module  $H^*(X)[z][[Q, t]]$  with the quantum connection defined above.

*Remark 1.1.9.* It is important to note that the quantum connection has a fundamental solution matrix  $S^X(t, z)$  given by

$$S_X(t, z) \phi = \phi + \sum_i \sum_{n, \beta} \frac{Q^\beta}{n!} \phi^i \left\langle \frac{\phi_i}{z - \psi}, \phi, t, \dots, t \right\rangle_{0, n+2, \beta}^X.$$

It satisfies the important equation

$$S_X^*(t, -z) S_X(t, z) = 1.$$

Using this formalism, the  $J$ -function is given by  $S_X^*(t, z) \mathbf{1} = z^{-1} J_X(t, z)$ .

**1.1.3 Givental formalism** The Givental formalism is a geometric way to package enumerative (CohFT) invariants cleanly. We begin by defining the symplectic space

$$\mathcal{H} := H^*(X, \Lambda)\langle\langle z^{-1} \rangle\rangle$$

with the symplectic form

$$\Omega(f, g) := \text{Res}_{z=0}(f(-z)g(z)).$$

This has a polarization by Lagrangian subspaces

$$\mathcal{H}_+ := H^*(X, \Lambda)[z], \quad \mathcal{H}_- := z^{-1}H^*(X, \Lambda)\langle\langle z^{-1} \rangle\rangle$$

giving  $\mathcal{H} \cong T^*\mathcal{H}_+$  as symplectic vector spaces. Choose Darboux coordinates  $\underline{p}, \underline{q}$  on  $\mathcal{H}$ . For example, there is a choice in Coates's thesis which gives a general element of  $\mathcal{H}$  as

$$\sum_{k \geq 0} \sum_i q_k^i \phi_i z^k + \sum_{\ell \geq 0} \sum_j p_\ell^j \phi^j (-z)^{-\ell-1}.$$

Taking the *dilaton shift*

$$q(z) = t(z) - z = -z + t_0 + t_1 z + t_2 z^2 + \cdots,$$

we can now think of  $\mathcal{F}^X$  has a formal function on  $\mathcal{H}_+$  near  $q = -z$ . This convention is called the *dilaton shift*.

Before we continue, we need to recast the string and dilaton equations in terms of  $\mathcal{F}^X$ . Write  $t_x = \sum t_k^i \phi_i$ . Then the string equation becomes

$$\partial_0^1 \mathcal{F}(t) = \frac{1}{2}(t_0, t_0) + \sum_{n=0}^{\infty} \sum_j t_{n+1}^j \partial_n^j \mathcal{F}(t)$$

and the dilaton equation becomes

$$\partial_1^1 \mathcal{F}(t) = \sum_{n=0}^{\infty} t_n^j \partial_n^j \mathcal{F}(t) - 2\mathcal{F}(t).$$

There are also an infinite series of topological recursion relations

$$\partial_{k+1}^i \partial_\ell^j \partial_m^k \mathcal{F}(t) = \sum_{a,b} \partial_k^i \partial_0^a \mathcal{F}(t) \eta^{ab} \partial_0^b \partial_\ell^j \partial_m^k \mathcal{F}(t).$$

We can make sense of these three relations for any (formal) function  $\mathcal{F}$  on  $\mathcal{H}_+$ .

Now let

$$\mathcal{L} = \left\{ (\underline{p}, \underline{q}) \in \mathcal{H} \mid \underline{p} = \mathbf{d}_{\underline{q}} \mathcal{F} \right\}$$

be the graph of  $\mathbf{d}\mathcal{F}$ . This is a formal germ at  $q = -z$  of a Lagrangian section of the cotangent bundle  $T^*\mathcal{H}_+$  and is therefore a formal germ of a Lagrangian submanifold in  $\mathcal{H}$ .

**Theorem 1.1.10.** *The function  $\mathcal{F}$  satisfies the string equation, dilaton equation, and topological recursion relations if and only if  $\mathcal{L}$  is a Lagrangian cone with vertex at the origin  $q = 0$  such that its tangent spaces  $L$  are tangent to  $\mathcal{L}$  exactly along  $zL$ .*

Because of this theorem,  $\mathcal{L}$  is known as the *Lagrangian cone*. It can be recovered from the  $J$ -function by the following procedure. First consider  $\mathcal{L} \cap (-z + z\mathcal{H}_-)$ . Via the projection to  $-z + H$  along  $\mathcal{H}_-$ , this can be considered as the graph of the  $J$ -function. Next, we consider the derivatives  $\frac{\partial J}{\partial t^i}$ , which form a basis of  $L \cap z\mathcal{H}_-$ , which is a complement to  $zL$  in  $L$ . Then we know that

$$z \frac{\partial J}{\partial t^i} \in zL \subset \mathcal{L},$$

so

$$z \frac{\partial^2 J}{\partial t^i \partial t^j} \in L \cap z\mathcal{H}_-.$$

Writing these in terms of the first derivatives  $\frac{\partial J}{\partial t^i}$  and using the fact that  $J$  is a solution of the quantum connection, so we recover the Frobenius structure of quantum cohomology.

We will now express some classical results in this formalism. Let  $X$  be a toric variety with toric divisors  $D_1, \dots, D_N$  such that  $D_1, \dots, D_k$  form a basis of  $H^2(X)$  and Picard rank  $k$ . Then define the *I-function*

$$I_X = ze^{\sum_{j=1}^k t_j D_j} \sum_{\beta} Q^{\beta} \frac{\prod_{j=1}^N \prod_{m=-\infty}^0 (D_j + mz)}{\prod_{j=1}^N \prod_{m=-\infty}^{\langle D_j, \beta \rangle} (D_j + mz)}.$$

**Theorem 1.1.11** (Mirror theorem). *The formal functions  $I_X$  and  $J_X$  coincide up to some change of variables, which if  $c_1(X)$  is semi-positive is given by components of the I-function.*

**Theorem 1.1.12** (Mirror theorem in this formalism). *For any  $t$ , we have*

$$I_X(t, z) \in \mathcal{L}.$$

Another direction in Gromov-Witten theory is the Virasoro constraints. In the original formulation, these involved very complicated explicit differential operators, but in the Givental formalism, there is a very compact formulation.

Define  $\ell^{-1} = z^{-1}$  and

$$\ell_0 = z \frac{d}{dz} + \frac{1}{2} + \mu + \frac{c_1(X) \cup -}{z}.$$

Then define

$$\ell_n = \ell_0(z\ell_0)^n.$$

**Theorem 1.1.13** (Genus-0 Virasoro constraints). *Suppose the vector field on  $\mathcal{H}$  defined by  $\ell_0$  is tangent to  $\mathcal{L}$ . Then the same is true for the vector fields defined by  $\ell_n$  for any  $n \geq 1$ .*

*Proof.* Let  $L$  be a tangent space to  $\mathcal{L}$ . Then if  $f \in zL \subset \mathcal{L}$ , the assumption gives us  $\ell_0 f \in L$ . But then  $z\ell_0 f \in zL$ , so  $\ell_0 z\ell_0 f = \ell_1 f \in L$ . Continuing, we obtain  $\ell_n f \in L$  for all  $n$ .  $\square$

Later, we will learn that the Quantum Riemann-Roch theorem can be stated in this formalism. Let  $\mathcal{L}^{\text{tw}}$  be the twisted Lagrangian cone (where the twisted theory will be defined next week).

**Theorem 1.1.14** (Quantum Riemann-Roch). *For some explicit linear symplectic transformaiton  $\Delta$ , we have  $\mathcal{L}^{\text{tw}} = \Delta \mathcal{L}$ .*

**1.1.4 Quantization** In the last part of the talk, we will briefly discuss the quantization formalism, which encodes the higher-genus theory. In Darboux coordinates  $p_a, q_b$ , we will quantize symplectic transformations by the standard rules

$$\widehat{q_a q_b} = \frac{q_a q_b}{\hbar}, \quad \widehat{q_a p_b} = q_a \frac{\partial}{\partial q_b}, \quad \widehat{p_a p_b} = \hbar \frac{\partial^2}{\partial q_a \partial q_b}.$$

This determines a differential operator acting on functions on  $\mathcal{H}_+$ .

We also need the genus- $g$  potential

$$\mathcal{F}_g^X := \sum_{\beta, n} \frac{Q^\beta}{n!} \langle t(\psi), \dots, t(\psi) \rangle_{g, n, \beta}^X$$

and the *total descendent potential*

$$\mathcal{D} := \exp \left( \sum_{g \geq 0} \hbar^{g-1} \mathcal{F}_g^X \right).$$

In this formalism, the Virasoro conjecture can be expressed as follows. Let  $L_n = \widehat{\ell}_n + c_n$ , where  $c_n$  is a carefully chosen constant.

**Conjecture 1.1.15** (Virasoro conjecture). *If  $L_{-1}\mathcal{D} = L_0\mathcal{D} = 0$ , then  $L_n\mathcal{D} = 0$  for all  $n \geq 1$ .*

In this formalism, the higher-genus version of the Quantum Riemann-Roch theorem takes the very simple form

**Theorem 1.1.16** (Quantum Riemann-Roch). *Let  $\mathcal{D}^{\text{tw}}$  be the twisted descendent potential. Then*

$$\mathcal{D}^{\text{tw}} = \widehat{\Delta} \mathcal{D}.$$

## 1.2 Quantum Riemann-Roch (Shaoyun, Feb 08)

We will state and prove the Quantum Riemann-Roch theorem in genus 0, following Coates-Givental.

**1.2.1 Twisted Gromov-Witten invariants** Again, let  $X$  be a smooth projective variety. Let  $E$  be a vector bundle on  $X$ . We should note that

$$\overline{\mathcal{M}}_{0, n+1}(X, \beta) \xrightarrow{\pi} \overline{\mathcal{M}}_{0, n}(X, \beta)$$

is the universal curve, and the universal morphism is simply  $\text{ev}_{n+1}$ . We will consider the sheaf

$$E_{0, n, \beta} := R\pi_* \text{ev}_{n+1}^* E \in K^0(\overline{\mathcal{M}}_{0, n}(X, \beta)).$$

We need to check that this is a well-defined  $K$ -theory class. Choose an ample line bundle  $L \rightarrow X$ . By definition, for  $N \gg 1$ , the cohomology

$$H^i(X, E \otimes L^N) = 0$$

whenever  $i \geq 1$ . This gives us an exact sequence

$$0 \rightarrow \ker(=: A) \rightarrow H^0(X, E \otimes L^N) \otimes L^{-N}(=: B) \rightarrow E \rightarrow 0.$$

For any stable map  $f: \Sigma \rightarrow X$  of positive degree, we obtain a long exact sequence

$$0 \rightarrow H^0(\Sigma, f^*E) \rightarrow H^1(\Sigma, f^*A) \rightarrow H^1(\Sigma, f^*B) \rightarrow H^1(\Sigma, f^*E) \rightarrow 0,$$

so we obtain

$$R^0\pi_* \text{ev}_{n+1}^* E - R^1\pi_* \text{ev}_{n+1}^* E = R^1\pi_* \text{ev}_{n+1}^* B - R^1\pi_* \text{ev}_{n+1}^* A.$$

This expresses  $E_{0,n,\beta}$  as a difference of vector bundles.

We will now introduce a *universal characteristic class*

$$\mathbf{c}(-) = \exp\left(\sum_{k=0}^{\infty} s_k \text{ch}_k(-)\right),$$

where  $s_0, s_1, s_2, \dots$  are formal variables and  $\text{ch}_k$  is the  $k$ -th Chern character

$$\frac{x_1^k}{k!} + \dots + \frac{x_r^k}{k!},$$

where  $x_i$  are the Chern roots.

**Example 1.2.1.** Let  $E \rightarrow X$  be a vector bundle and equip it with the fiberwise  $\mathbb{C}^*$ -action by scaling. Let  $\lambda$  be the equivariant parameter and  $\rho_i$  be the Chern roots. Then

$$e(E) = \sum_i (\lambda + \rho_i).$$

We then rewrite

$$\begin{aligned} \prod (\lambda + \rho_i) &= \exp\left(\sum_i \left(\log \lambda - \sum_k \frac{(-\rho_i)^k}{k\lambda^k}\right)\right) \\ &= \exp\left(\text{ch}_0(E) \log \lambda + \sum_{k>0} \frac{(-1)^{k-1}(k-1)!}{\lambda^k} \text{ch}_k(E)\right), \end{aligned}$$

so for the (equivariant Euler class), we obtain

$$\begin{aligned} s_0 &= \log \lambda \\ s_k &= \frac{(-1)^{k-1}(k-1)!}{\lambda^k}, \quad k > 0. \end{aligned}$$

We are now ready to define the  $(E, \mathbf{c})$ -twisted Gromov-Witten invariants.

**Definition 1.2.2.** Define the *twisted Gromov-Witten invariants* by

$$\left\langle \alpha_1 \psi_1^{k_1}, \dots, \alpha_n \psi_n^{k_n} \right\rangle_{0,n,\beta}^{X,(E,\mathbf{c})} := \int_{[\overline{\mathcal{M}}_{0,n}(X,\beta)]^{\text{vir}}} \prod_{i=1}^n \text{ev}_i^*(\alpha_i) \psi_i^{k_i} \cup \mathbf{c}(E_{0,n,\beta})$$

for  $\alpha_i \in H^*(X)$  and  $k_i \in \mathbb{Z}_{\geq 0}$ .

We will now construct the Lagrangian cone for the twisted theory. Let  $R$  be the coefficient ring containing  $s_0, s_1, \dots$  and define

$$\mathcal{H}_X^{\text{tw}} := H^*(X) \otimes R\langle z^{-1} \rangle[[Q]].$$

We also introduce the *twisted Poincaré pairing*

$$(a, b)_{(E, \mathbf{c})} = \int_X a \cup b \cup \mathbf{c}(E).$$

The symplectic structure is defined by

$$\Omega_{\text{tw}}(f, g) = \text{Res}_{z=0}(f(-z)g(z))_{(E, \mathbf{c})}.$$

There is a polarization

$$\mathcal{H}_X^{\text{tw}} = \mathcal{H}_+^{\text{tw}} \oplus \mathcal{H}_-^{\text{tw}}$$

with

$$\begin{aligned} \mathcal{H}_+^{\text{tw}} &:= H^*(X) \otimes R[z][[Q]] \\ \mathcal{H}_-^{\text{tw}} &:= H^*(X) \otimes R[[z]][[Q]]. \end{aligned}$$

Finally, we have the *twisted genus-0 descendent potential*

$$\mathcal{F}_{X, \text{tw}}^0(t) := \sum_{\beta, n} \frac{Q^\beta}{n!} \langle t, \dots, t \rangle_{0, n, \beta}^{X, (E, \mathbf{c})}.$$

Identifying  $\mathcal{H}_X^{\text{tw}}$  with  $T^*\mathcal{H}_+^{\text{tw}}$ , we obtain the twisted Lagrangian cone  $\mathcal{L}_X^{\text{tw}}$  as the graph of  $d\mathcal{F}_{X, \text{tw}}^0$ . Denote the untwisted Lagrangian cone as  $\mathcal{L}_X$ .

**Theorem 1.2.3.** *We have*

$$\mathcal{L}_X^{\text{tw}} = \Delta \mathcal{L}_X,$$

where

$$\Delta = \exp \left( \sum_{m \geq 0} \sum_{\ell \geq 0} s_{2m-1+\ell} \frac{B_{2m}}{(2m)!} \text{ch}_\ell(E) z^{2m-1} \right).$$

Here, the Bernoulli numbers  $B_{2m}$  are defined by

$$\frac{t}{1 - e^{-t}} = \frac{t}{2} + \sum_{m \geq 0} \frac{B_{2m}}{(2m)!} t^{2m}.$$

**1.2.2 Proof of Theorem 1.2.3** The idea is to use the Grothendieck-Riemann-Roch theorem.

**Proposition 1.2.4.** *We can write*

$$[\overline{\mathcal{M}}_{0,n}(X, \beta)]^{\text{vir}} \cap \text{ch}_k(E_{0,n,\beta}) = \pi_* \left( \sum_{\substack{r+\ell=k+1 \\ r, \ell \geq 0}} \frac{B_r}{r!} \text{ch}_\ell(\text{ev}_{n+1}^* E) \Psi(r) \right),$$

where

$$\begin{aligned} \Psi(r) &= \psi_{n+1}^r \cap [\overline{\mathcal{M}}_{0,n+1}(X, \beta)]^{\text{vir}} \\ &\quad - \sum_{i=1}^n (\sigma_i)_* (\psi_i^{n-1} \cap [\overline{\mathcal{M}}_{0,n}(X, \beta)]^{\text{vir}}) \\ &\quad + \frac{1}{2} j_* \left( \sum_{\substack{a+b=r-2 \\ a, b \geq 0}} (-1)^a \psi_+^a \psi_i^b \cap [\tilde{Z}_{0,n+1,\beta}]^{\text{vir}} \right). \end{aligned}$$

Here,  $Z_{0,n+1,\beta}$  is formed by the nodes of  $\pi$ ,  $\tilde{Z}_{0,n+1,\beta}$  is a double cover of  $Z_{0,n+1,\beta}$  formed by a choice of branch of the nodes,  $\psi_+$  and  $\psi_-$  are the  $\psi$ -classes at the two branches of the nodes, and

$$j: \tilde{Z}_{0,n+1,\beta} \rightarrow Z_{0,n+1,\beta} \rightarrow \overline{\mathcal{M}}_{0,n+1}(X, \beta)$$

is the “inclusion.”

*Proof.* We will first assume that  $\overline{\mathcal{M}}_{0,n+1}(X, \beta)$ ,  $\overline{\mathcal{M}}_{0,n}(X, \beta)$ , and  $Z_{0,n+1,\beta}$  are all smooth and that  $\pi(Z_{0,n+1,\beta})$  is a normal crossings divisor. In general, we need a Cartesian diagram

$$\begin{array}{ccc} & \text{ev}_{n+1}^* E & \longrightarrow E \\ & \swarrow & \searrow \\ \overline{\mathcal{M}}_{0,n+1}(X, \beta) & \longrightarrow & \mathcal{C} \\ & \swarrow & \searrow \\ & Z_{0,n+1,\beta} & Z \\ \downarrow & & \downarrow \\ \overline{\mathcal{M}}_{0,n}(X, \beta) & \longrightarrow & \mathcal{M}. \end{array}$$

Continuing in the ideal situation, we apply Grothendieck-Riemann-Roch<sup>1</sup> to obtain

$$\begin{aligned} \text{ch}(E_{0,n,\beta}) &= \text{ch}(R\pi_* \text{ev}_{n+1}^* E) \\ &= \pi_*(\text{ch}(\text{ev}_{n+1}^* E) \cdot \text{td}^\vee \Omega_\pi), \end{aligned}$$

where  $\text{td}^\vee$  is the dual Todd class, defined by  $\frac{-x}{1-e^{ix}}$ , and  $\Omega_\pi$  is the sheaf of relative differentials.

We then have two short exact sequences

$$0 \rightarrow \Omega_\pi \rightarrow \omega_\pi \rightarrow \mathcal{O}_{Z_{0,n+1,\beta}} \rightarrow 0$$

and

$$0 \rightarrow \omega_\pi \rightarrow L_{n+1} \rightarrow \bigoplus_{i=1}^n \mathcal{O}_{D_i} \rightarrow 0,$$

where  $D_i$  is the divisor where the marked points  $i, n+1$  collide and their component has exactly three special points. Now we obtain

$$\Omega_\pi = L_{n+1} - \sum_{i=1}^n \mathcal{O}_{D_i} - \mathcal{O}_{Z_{0,n+1,\beta}}$$

in  $K$ -theory. Using the facts that  $c_1(L_{n+1}) = \psi_{n+1}$ ,  $D_i \cap D_j = \emptyset$  for  $i \neq j$ , and  $D_i \cap Z_{0,n+1,\beta} = \emptyset$ , we see that  $L_{n+1}$  is trivial when restricted to  $D_i$  and  $Z_{0,n+1,\beta}$ . Now we apply the dual Todd class.

**Lemma 1.2.5.** *If  $x_1 \cup x_2 = 0$ , then*

$$(\text{td}^\vee(x_1) - 1)(\text{td}^\vee(x_2) - 1) = 0.$$

<sup>1</sup>We need to be careful about directly applying Grothendieck-Riemann-Roch in the stacky setting (and in general we are only quasi-smooth).

Using the lemma, we obtain

$$\begin{aligned} \mathrm{td}^\vee(\Omega_\pi) &= \mathrm{td}^\vee(L_{n+1}) \prod_{i=1}^n \mathrm{td}^\vee(-\mathcal{O}_{D_i}) \mathrm{td}^\vee(\mathcal{O}_{Z_{0,n+1,\beta}})^{-1} \\ &= 1 + (\mathrm{td}^\vee(L_{n+1}) - 1) + \sum_{i=1}^n \left( \frac{1}{\mathrm{td}^\vee(\mathcal{O}_{D_i})} - 1 \right) + \left( \frac{1}{\mathrm{td}^\vee(\mathcal{O}_{Z_{n+1,\beta}})} - 1 \right). \end{aligned}$$

The first term in the statement comes from the dual Todd class of  $L_{n+1}$ , the second comes from

$$0 \rightarrow \mathcal{O}(-D_i) \rightarrow \mathcal{O} \rightarrow \mathcal{O}_{D_i} \rightarrow 0$$

and the relation between  $\mathcal{O}(-D_i)$  and  $L_i$ , and the last term can be found in Appendix A of Coates-Givental.  $\square$

To obtain the Quantum Riemann-Roch theorem, we use the previous proposition and manipulate the generating function. If  $E$  is convex and  $Y \subset X$  is a complete intersection defined by  $E$ , then  $\mathcal{L}_X^{\mathrm{tw}}$  is closely related to  $\mathcal{L}_Y$ , so we are able to study the Gromov-Witten theory of  $Y$  using this.

### 1.3 Shift operators (Melissa, Feb 15)

Let  $X$  be a semiprojective smooth variety. This means that  $X$  is projective over its affinization. Also assume that  $X$  has an action by  $T = (\mathbb{C}^\times)^m$  such that all  $T$ -weights in  $H^0(X, \mathcal{O})$  are contained in a strictly convex cone in  $\mathrm{Hom}(T, \mathbb{C}^\times)_{\mathbb{R}}$  and  $H^0(X, \mathcal{O})^T = \mathbb{C}$ . All such  $X$  imply that

- (a) The fixed locus  $X^T$  is projective;
- (b) The  $T$ -variety  $X$  is equivariantly formal. This means that  $H_T^*(X)$  is a free module over  $H_T^*(\mathrm{pt}) = \mathbb{Q}[\lambda] := \mathbb{Q}[\lambda_1, \dots, \lambda_m]$  and there is a non-canonical isomorphism

$$H_T^*(X) \cong H^*(X) \otimes H_T^*(\mathrm{pt})$$

as  $H_T^*(\mathrm{pt})$ -modules.

- (c) The evaluation maps  $\mathrm{ev}_i: X_{0,n,d} \rightarrow X$  are proper.

Using (b), we may choose a basis  $\{\phi_i\}_{i=0}^N$  of  $H_T^*(X)$  over  $H_T^*(\mathrm{pt})$ . Let  $\tau^i$  be the dual coordinates.

**1.3.1 Equivariant big quantum cohomology** Let  $(-, -)$  be the  $T$ -equivariant Poincaré pairing, which in general takes values in  $\mathbb{Q}(\lambda)$ . Then the  $T$ -equivariant big quantum product is defined by

$$\begin{aligned} (\phi_i \star_\tau \phi_j, \phi_k) &= \langle \phi_i, \phi_j, \phi_k \rangle_{0,3}^{X,T} \\ &= \sum_{d,n} \frac{Q^d}{n!} \langle \phi_i, \phi_j, \phi_k, \tau, \dots, \tau \rangle_{0,n+3,d}^{X,T}. \end{aligned}$$

This can also be defined using the evaluation maps

$$(\mathrm{ev}_i)_*: H_T^*(X_{0,n+3,d}) \rightarrow H_T^{*-2(c_1(X) \cdot d + n)}(X)$$

as

$$\phi_i \star_\tau \phi_j = \sum_{d,n} \frac{Q^d}{n!} (\mathrm{ev}_3)_* \left( \mathrm{ev}_1^*(\phi_i) \mathrm{ev}_2^*(\phi_j) \prod_{i=4}^{n+3} \mathrm{ev}_i^*(\tau) \cap [X_{0,n+3,d}]^{\mathrm{vir}} \right) \in H_T^*(X) \llbracket Q \rrbracket \llbracket \tau_0, \dots, \tau_n \rrbracket.$$

### 1.3.2 Quantum connection

We will define

$$\nabla_i: H_T^*(X)[z][[Q]][\tau] \rightarrow z^{-1}H_T^*(X)[z][[Q]][\tau^0, \dots, \tau^N]$$

by setting

$$\nabla_i = \frac{\partial}{\partial \tau^i} + \frac{1}{z}(\phi_i \star).$$

We can view  $z$  as the loop variable by setting  $\hat{T} = T \times \mathbb{C}^\times$ . If the extra copy of  $\mathbb{C}^\times$  acts trivially on  $X$ , then

$$H_{\hat{T}}^*(X) = H_T^*(X)[z].$$

This has a fundamental solution

$$M(\tau): H_{\hat{T}}^*(X)[[Q, \tau]] \rightarrow H_{\hat{T}}^*(X)_{\text{loc}}[[Q, \tau]]$$

where

$$H_{\hat{T}}^*(X)_{\text{loc}} := H_T^*(X) \otimes_{\mathbb{Q}[\lambda, z]} \mathbb{Q}(\lambda(z)).$$

This satisfies the differential equation

$$z \frac{\partial}{\partial \tau^i} M(\tau) = M(\tau)(\phi_i \star),$$

which is equivalent to

$$\frac{\partial}{\partial \tau^i} \circ M(\tau) = M(\tau) \circ \nabla_i.$$

The solution has the form

$$(M(\tau)\phi_i, \phi_j) = (\phi_i, \phi_j) + \left\langle\left\langle \phi_i, \frac{\phi_j}{z - \psi} \right\rangle\right\rangle_{0,2}^{X,T}.$$

**1.3.3 Shift operators** Let  $k: \mathbb{C}^\times \rightarrow T$  be a cocharacter of  $T$ . Then define a  $\hat{T}$ -action  $\rho_k$  on  $X$  by

$$\rho_k(t, x)x = tu^k \cdot x$$

for  $t \in T, u \in \mathbb{C}^\times, x \in X$ . Under the group automorphism

$$\phi_k: \hat{T} \rightarrow \hat{T} \quad \phi_k(t, u) = (tu^{-k}, u),$$

the identity map  $(X, \rho_0) \rightarrow (X, \rho_k)$  is  $\hat{T}$ -equivariant, so we obtain isomorphisms

$$\Phi_k: H_{\hat{T}, \rho_0}^*(X) \rightarrow H_{\hat{T}, \rho_k}^*(X).$$

Now define the bundle

$$E_k = (X \times (\mathbb{C}^2 \setminus 0)) / \mathbb{C}^\times,$$

where  $\mathbb{C}^\times$  acts by

$$s \cdot (x, v_1, v_2) = (s^k x, s^{-1}v_1, s^{-1}v_2).$$

This is an  $X$ -bundle over  $\mathbb{P}^1$  with an action on  $\hat{T}$  by

$$(t, u) \cdot [x, (v_1, v_2)] = [t \cdot x, (v_1, uv_2)].$$

Setting  $0 = [1, 0]$  and  $\infty = [0, 1]$ , we see that  $\hat{T}$  acts on  $X_0$  by  $\rho_0$  and  $X_\infty$  by  $\rho_k$ .

**Definition 1.3.1.** A cocharacter  $k: \mathbb{C}^\times \rightarrow T$  is *seminegative* if all weights of  $H^0(X, \mathcal{O})$  are nonpositive with respect to  $k$  and is *negative* if all nonzero weights of  $H^0(X, \mathcal{O})$  are negative.

**Lemma 1.3.2.** If  $k$  is seminegative, then  $E_k$  is semiprojective.

Now let  $\pi: E_k \rightarrow \mathbb{P}^1$  be the projection. We now consider *section classes*, which are those effective classes in  $H_2(E_k, \mathbb{Z})$  satisfying  $\pi_* d = [\mathbb{P}^1]$ . For the  $\mathbb{C}^\times$ -action on  $X$  given by  $k$ , there is a unique fixed component  $F_{\min}$  whose normal weights are all positive (one way to see this is to consider the moment map of the corresponding circle action). Therefore, there is a minimal section class  $\sigma_{\min}$  corresponding to  $F_{\min}$ .

**Lemma 1.3.3.** Given  $\tau \in H_T^*(X)$ , there exists  $\hat{\tau} \in H_{\hat{T}}^*(E_k)$  such that  $\hat{\tau}|_{X_0} = \tau$  and  $\hat{\tau}|_{X_\infty} = \Phi_k(\tau)$ .

**Lemma 1.3.4.** If  $k$  is seminegative, then

$$\text{Eff}(E_k)^{\text{sec}} = \sigma_{\min} + \text{Eff}(X).$$

**Definition 1.3.5.** Let  $k: \mathbb{C}^\times \rightarrow T$  be seminegative. Given  $\tau \in H_T^*(X)$ , we define the *shift operator*

$$\tilde{S}_k: H_{\hat{T}, \rho_0}^*(X)[[Q]] \rightarrow H_{\hat{T}, \rho_k}^*(X)[[Q]]$$

by the formula

$$(\tilde{S}_k(\tau)\alpha, \beta) = \sum_{\hat{d} \in \text{Eff}(E_k)^{\text{sec}}} \frac{Q^{\hat{d} - \sigma_{\min}}}{n!} \langle (\iota_0)_* \alpha, (\iota_\infty)_* \beta, \hat{\tau}, \dots, \hat{\tau} \rangle_{0, n+2, \hat{d}}^{E_k, \hat{T}}$$

where  $\alpha \in H_{\hat{T}, \rho_0}^*(X)$  and  $\beta \in H_{\hat{T}, \rho_k}^*(X)$ . We also define

$$S_k(\tau) = \Phi_k^{-1} \circ \hat{S}_k(\tau).$$

**Theorem 1.3.6.** We have the formula

$$M(\tau) \circ S_k(\tau) = S_k \circ M(\tau),$$

where  $S_k$  is defined via the commutative diagram

$$\begin{array}{ccc} H_{\hat{T}}^*(X)_{\text{loc}} & \xrightarrow{S_k} & H_{\hat{T}}^*(X)_{\text{loc}} \\ \downarrow & & \downarrow \iota^* \\ H_{\hat{T}}^*(X^T)_{\text{loc}} & \xrightarrow{\oplus_i \Delta_i(k) e^{-2k\delta_\lambda}} & H_{\hat{T}}^*(X^T)_{\text{loc}}. \end{array}$$

Here, we define

$$\Delta_i(k) = Q^{\sigma_i - \sigma_{\min}} \prod_{\alpha} \prod_{j=1}^{\text{rk } N_{i,\alpha}} \frac{\prod_{c=-\infty}^0 (\rho_{i,\alpha,j} + \alpha + cz)}{\prod_{c=-\infty}^{-\alpha \cdot k} (\rho_{i,\alpha,j} + \alpha + cz)} \in H_{\hat{T}}^*(F_i)_{\text{loc}}[[Q]],$$

where

$$N_i = N_{F_i/X} = \bigoplus_{\alpha} N_{i,\alpha}$$

is the normal bundle of  $F_i$  in  $X$  and  $\rho_{i,\alpha,j}$  are its Chern roots.

The idea of the proof is to decompose

$$E_{k,0,n+2,\hat{d}}^{\hat{T}} = \bigsqcup_i \bigsqcup_{I_1 \cup I_2 = [n+2]} \bigsqcup_{d_0 + d_\infty + \hat{\sigma} = \hat{d}} (X_0)_{0,I_1 \sqcup p, d_0}^T \times_{F_i} (X_\infty)_{0,I_2 \sqcup q, d_\infty}^T.$$

Using the exact sequence

$$0 \rightarrow \text{Aut}(C, x) \rightarrow \text{Def}(f) \rightarrow T^1 \rightarrow \text{Def}(C, x) \rightarrow \text{Obs}(f) \rightarrow T^2 \rightarrow 0,$$

we obtain the explicit formulae

$$\begin{aligned} \text{Aut}(C, x)^m &= \text{Aut}(C_0, x_0)^m + \text{Aut}(C_\infty, x_\infty)^m \\ \text{Def}(C, x)^m &= \text{Def}(C_0, x_0)^m \oplus \text{Def}(C_0, x_0)^m \oplus T_p C_0 \otimes T_p \mathbb{P}^1 \oplus T_q C_\infty \otimes T_q \mathbb{P}^1. \end{aligned}$$

This gives the virtual normal bundle, and using virtual localization, we obtain

$$(\tilde{\mathcal{S}}_k(\tau)\alpha, \beta) = (\tilde{\mathcal{S}}_k M(\tau, z)\alpha, M'(\tau', -z)\beta),$$

where

$$M'(\tau', z) = \Phi_k \circ M(\tau, z) \circ \Phi_k^{-1}.$$

Using the unitarity property of  $M$ , we obtain the desired result.

## Quantum cohomology of projective bundles

### 2.1 Mirror theorem (Che, Feb 22)

**2.1.1 Setup** Let  $X$  be a smooth projective variety,  $\{\phi_i\}_{i=0}^s$  be a basis of  $H^*(X)$ ,  $\{\phi^i\}_{i=0}^s$  be the dual basis, and

$$\tau = \sum_{i=0}^s \tau^i \phi_i \in H^*(X).$$

We will let

$$J_X(\tau) = 1 + \frac{\tau}{z} + z^{-1} \sum_{d,n} \sum_{j=0}^s \left\langle \tau, \dots, \tau, \frac{\phi_j}{z - \psi} \right\rangle_{0,n+1,d}^X \frac{Q^d}{n!},$$

which is the  $J$ -function in Definition 1.1.3 multiplied by  $z^{-1}$ .<sup>1</sup> Also, recall the inverse of the fundamental solution of the quantum D-module

$$M_X(\tau) \in \text{End}(H^*(X))[z^{-1}][[Q, \tau]],$$

which is defined by

$$(\overline{M}_X(\tau)\phi_i, \phi_j) = (\phi_i, \phi_j)_X + \sum_{d,n} \left\langle \phi_i, \tau, \dots, \tau, \frac{\phi_j}{z - \psi} \right\rangle_{0,n+2,d}^X \frac{Q^d}{n!}.$$

*Remark 2.1.1.* By the string equation, we have

$$J_X(\tau) = M_X(\tau) \cdot 1.$$

**2.1.2 The vector bundle case** Now let  $V \rightarrow B$  be a vector bundle with  $\text{rk } V \geq 2$ . This has an action of  $\mathbb{C}^\times$  scaling the fibers. Then we have

$$H_{\mathbb{C}^\times}^*(V) = H^*(B) \otimes \mathbb{C}[\lambda].$$

Now we may take  $\tau^0, \dots, \tau^s$  to be  $\mathbb{C}[\lambda]$ -valued coordinates.

*Remark 2.1.2.* Equivariant localization is required to define the Gromov-Witten invariants of  $V$ , which lie in  $\mathbb{C}[\lambda, \lambda^{-1}]$ .

<sup>1</sup>This is in fact the older definition of the  $J$ -function, but the one in Definition 1.1.3 lies on the Lagrangian cone

In order to avoid this issue, we will assume that  $V^\vee$  is globally generated. This implies that  $V$  is semiprojective, meaning that the evaluation maps  $\text{ev}: V_{0,n,d} \rightarrow V$  are proper. As before, we may define the fundamental solution

$$M_V(\tau) \in \text{End}(H^*(B))[\lambda, z^{-1}][[Q, \tau]]$$

and the  $J$ -function

$$J_V^\lambda(\tau) = M_V(\tau) \cdot 1.$$

Because the evaluation maps are proper, they can be defined without localization.

### 2.1.3 Statement and discussion of the mirror theorem

**Theorem 2.1.3.** *Define the  $H^*(\mathbb{P}(V))$ -valued function*

$$I_{\mathbb{P}(V)}(\tau, t) = \sum_{k=0}^{\infty} \frac{e^{pt/z} q^k e^{kt}}{\prod_{c=1}^k \prod_{\delta} (p + \delta + cz)} J_V^{p+kz}(\tau),$$

where  $\delta$  are the Chern roots of  $V$ ,  $q$  is the Novikov variable, and  $p = c_1(\mathcal{O}_{\mathbb{P}(V)}(1))$ . Then  $zI_{\mathbb{P}(V)}(\tau, t)$  lies on the Lagrangian cone of  $\mathbb{P}(V)$ .

Let  $\mathcal{L}_X^{\text{orig}}$  be the Lagrangian cone for  $X$ , which has the explicit form

$$(2.1) \quad -z + t(z) + \sum_{d,n} \sum_{k \geq 0} \sum_{i=0}^s \frac{\phi^i}{(-z)^{k+1}} \left\langle t(\psi), \dots, t(\psi), \phi_i \psi^k \right\rangle_{0,n+1,d}^X \frac{Q^d}{n!}.$$

**Definition 2.1.4.** For a set of variables  $x = (x_1, x_2, \dots)$ , we say that  $f \in \mathcal{H}_X[[x]]$  is a  $\mathbb{C}[[Q, x]]$ -valued point on  $\mathcal{L}_X^{\text{orig}}$  if  $f$  is of the form 2.1 for some  $t(z) \in \mathcal{H}_+[[x]]$  with  $t(z)|_{Q=x=0} = 0$ .

**Example 2.1.5.** The point  $zJ_X(\tau)|_{z \mapsto -z}$  is a  $\mathbb{C}[[Q, \tau]]$ -valued point on  $\mathcal{L}_X^{\text{orig}}$ .

Given this, define  $\mathcal{L}_X := \mathcal{L}_X^{\text{orig}}|_{z \mapsto -z}$ . By Theorem 1.1.10, we obtain

$$L_X = \bigcup_{\tau} zM_X(\tau)\mathcal{H}_+,$$

which means that any  $\mathbb{C}[[Q, x]]$ -valued point on  $\mathcal{L}_X$  can be written as  $zM_X(\tau)f$  for some  $\tau \in H^*(X)[[Q, x]]$  and  $f \in \mathcal{H}_+[[x]]$  such that  $\tau|_{Q=x=0} = 0$  and  $f|_{Q=x=0} = 1$ . This property will be used to construct the Fourier transform later.

**2.1.4 Proof of Theorem 2.1.3** We will now sketch a proof of Theorem 2.1.3. First, we will need Quantum-Riemann-Roch for a vector bundle  $W \rightarrow X$  in two cases:

- (a) When the vector bundle  $W$  is convex, which means that  $H^1(C, f^*W) = 0$  for all stable maps  $f: C \rightarrow X$  of genus 0, and  $\mathbf{c} = e(\lambda)$  is the equivariant Euler class, which corresponds to setting

$$s_k = \begin{cases} \log \lambda & k = 0 \\ (-1)^{k-1} (k-1)! \lambda^{-k} & k > 0. \end{cases}$$

- (b) When  $W$  is globally generated and  $\mathbf{c} = e_\lambda^{-1}$ .

In the first case, we obtain the Gromov-Witten invariants of the zeroes of a regular section  $Z \subset X$  of  $W$  via

$$\lim_{\lambda \rightarrow 0} \left\langle \alpha_1 \psi^{k_1}, \dots, \alpha_n \psi^{k_n} \right\rangle_{0,n,d}^{X,(W,e_\lambda)} = \sum_{i_* d' = d} \left\langle i^* \alpha_1 \psi_1^{k_1}, \dots, \alpha_n \psi_n^{k_n} \right\rangle_{0,n,d'}^Z.$$

In the second case, we obtain the Gromov-Witten invariants of  $W$  via

$$\left\langle \alpha_1 \psi^{k_1}, \dots, \alpha_n \psi^{k_n} \right\rangle_{0,n,d}^{X,(W,e_\lambda^{-1})} = \left\langle i^* \alpha_1 \psi_1^{k_1}, \dots, \alpha_n \psi_n^{k_n} \right\rangle_{0,n,d}^W.$$

We are now ready to begin the proof. Because  $V^\vee$  is globally generated, there is a surjection

$$\mathcal{O}^{\oplus N} \rightarrow V^\vee.$$

This gives an exact sequence

$$0 \rightarrow V \rightarrow \mathcal{O}^{\oplus N} \rightarrow Q \rightarrow 0$$

embedding  $\mathbb{P}(V) \hookrightarrow B \times \mathbb{P}^{N-1}$ . By a result of Brown-Elezi, we have

$$J_{B \times \mathbb{P}^{N-1}}(\tau, t) = \sum_{k=0}^{\infty} \frac{e^{pt/z} q^k e^{kt}}{\prod_{c=1}^k (p + cz)^N} J_B(\tau).$$

Now define

$$Q(1) := \pi_1^* Q \otimes \pi_2^* \mathcal{O}(1)$$

on  $B \times \mathbb{P}^1$ . This has a section  $s$  given by

$$\pi_2^* \mathcal{O}(-1) \rightarrow \mathcal{O}_{B \times \mathbb{P}^{N-1}}^{\oplus N} \rightarrow \pi_1^* Q$$

which satisfies  $s^{-1}(0) = \mathbb{P}(V)$ . Because  $Q(1)$  is convex, we use Quantum-Riemann-Roch in case (a) to relate the Gromov-Witten theory of  $\mathbb{P}(V)$  to the  $(Q(1), e_\lambda)$ -twisted Gromov-Witten theory. We now require two more technical ingredients.

*Moving points on the Lagrangian cone via differential operators*

**Lemma 2.1.6.** *Let  $x = (x_1, x_2, \dots)$  and  $y = (y_1, y_2, \dots)$  be formal variables. Let*

$$F \in \mathbb{C}[z][[x]] \langle z \partial_{x_1}, z \partial_{x_2}, \dots \rangle [[Q, y]]$$

*be a differential operator. Then  $\exp(F/z)$  preserves  $\mathbb{C}[[Q, x, y]]$ -valued points on  $\mathcal{L}_X$ .*

**Definition 2.1.7.** A  $\mathbb{C}[[Q, \tau, y]]$ -valued point  $f$  on  $\mathcal{L}_X$  is called a *miniversal slice* if

$$f|_{Q=y=0} = z + \tau + \mathcal{O}(z^{-1}).$$

For example, the  $J$ -function is a miniversal slice.

**Lemma 2.1.8.** *Any miniversal slice on  $\mathcal{L}_X$  can be obtained from  $zJ_X(\tau)$  by applying  $\exp(F/z)$  for some differential operator  $F$  as in the previous lemma satisfying  $F|_{Q=y=0} = 0$ .*

The rest of the proof (ignoring convergence issues) First, we introduce

$$\Delta_W^\lambda := e^{\text{rk}(W)(\lambda \log \lambda - \lambda)/z} \Delta_{(W, e_\lambda^{-1})}.$$

Because  $\log \Delta_W^\lambda$  and  $\log \Gamma(x)$  have similar asymptotic expansions, we have

$$\Delta_W^{\lambda+kz} / \Delta_W^\lambda = \prod_{c=1}^k \prod_{\delta} (\lambda + \delta + cz).$$

Using the exact sequence

$$0 \rightarrow V \rightarrow \mathcal{O}^{\oplus N} \rightarrow Q \rightarrow 0,$$

we see that

$$\Delta_V^\lambda \Delta_Q^\lambda = \Delta_{\mathcal{O}^{\oplus N}}^\lambda,$$

which preserves the Lagrangian cone  $\mathcal{L}_B$ . We see that

$$\Delta_Q^\lambda : \mathcal{L}_{B, (V, e_\lambda^{-1})} \rightarrow \mathcal{L}_B.$$

Applying Quantum-Riemann-Roch in case (b), we see that

$$zJ_V^\lambda(z) \in L_{B, (V, e_\lambda^{-1})},$$

and thus

$$\Delta_Q^\lambda zJ_F^\lambda(z) \in \mathcal{L}_B.$$

By Lemma 2.1.8, there exists  $F$  such that

$$\Delta_Q^\lambda zJ_V^\lambda(z) = e^{F(\lambda)/z} zJ_B(\tau).$$

By Lemma 2.1.6, we obtain

$$e^{F(\lambda+z\partial_t)/z} J_{B \times \mathbb{P}^{N-1}}(\tau, t) \in \mathcal{L}_{B \times \mathbb{P}^{N-1}}.$$

Now we compute

$$\begin{aligned} I^\lambda(\tau, t) &:= (\Delta_{Q(1)}^\lambda)^{-1} e^{F(\lambda+z\partial_t)/z} J_{B \times \mathbb{P}^{N-1}}(\tau, t) \\ &= \sum_{k=0}^{\infty} \frac{e^{pt/z} q^k e^{kt}}{\prod_{c=1}^k (p + cz)^N} (\Delta_{Q(1)}^\lambda)^{-1} e^{F(\lambda+p+kz)} J_B(\tau) \\ &= \sum_{k=0}^{\infty} \frac{e^{pt/z} q^k e^{kt}}{\prod_{c=1}^k (p + cz)^N} (\Delta_{Q(1)}^\lambda)^{-1} (\Delta_Q^{\lambda+p})^{-1} \Delta_Q^{\lambda+p+kz} J_V^{\lambda+p+kz} \\ &= \sum_{k \geq 0} e^{pt/z} q^k e^{kt} \frac{\prod_{c=1}^k \prod_{\varepsilon} (\lambda + p + \varepsilon + cz)}{\prod_{c=1}^k (p + cz)^N} J_V^{\lambda+p+kz}, \end{aligned}$$

where  $\varepsilon$  runs over the Chern roots of  $Q$ . Taking the non-equivariant limit  $\lambda \rightarrow 0$ , we obtain the  $I(\tau, t)$  in the statement of Theorem 2.1.3.

## 2.2 Fourier transform (Kostya, Feb 29)

Technically, there are two different Fourier transforms:

1. The discrete Fourier transform  $\text{QDM}_{S^1}(V) \xrightarrow{\text{FT}} \text{QDM}(\mathbb{P}(V));$
2. The continuous Fourier transform  $\text{QDM}(\mathbb{P}(V))_{\text{loc}} \rightarrow \bigoplus_{i=0}^{r-1} \text{QDM}(B).$

**2.2.1 Quantum  $D$ -modules and symplectic spaces** Let  $V \rightarrow B$  be a rank  $r$  vector bundle. The quantum  $D$ -module of  $V$  will be

$$H_{S^1}^*(V) \otimes \mathbb{C}[z, \lambda][[Q, \tau]],$$

where  $\lambda$  is the equivariant variable,  $Q$  is the Novikov variable, and  $\tau = \{\tau^{i,k}\}$  for  $i$  counting a basis of  $H^*(V)$  and  $k$  records the degree of  $\lambda$ . It is equipped with the Dubrovin connection

$$\nabla: \text{QDM}_{S^1}(V) \rightarrow z^{-1} \text{QDM}_{S^1}(V)$$

given by

$$\begin{aligned} \nabla_{\tau^{i,k}} &= \frac{\partial}{\partial \tau^{i,k}} + z^{-1} \lambda^k (\phi_i \star -) \\ \nabla_{\xi Q \partial_Q} &= \xi Q \partial_Q + z^{-1} (\xi \star -) \\ \nabla_{z \partial_z} &= z \partial_z - z^{-1} (E_{S^1} \star -) + \mu_{S^1}. \end{aligned}$$

Note the last line is only  $\mathbb{C}$ -linear. Recall the fundamental solution  $M_V^{-1}(\tau, z)$  is a fundamental solution in the cohomology directions (but not the conformal direction) in the sense that

$$\begin{aligned} \partial_{\tau^{i,k}} M_V &= M_V \nabla_{\tau^{i,k}} \\ (\varepsilon Q \partial_Q + z^{-1} \xi) M_V &= M_V \nabla_{\varepsilon Q \partial_Q} \end{aligned}$$

and intertwines the shift operator by

$$S M_V = M_V S(\tau),$$

where

$$S = e_\lambda(V) e^{z \partial_\lambda}.$$

Now, the symplectic space for  $V$  is

$$\mathcal{H}_V^{S^1} := H_{S^1}^*(V) \langle z^{-1} \rangle [[Q, \tau]]$$

with its Lagrangian cone  $\mathcal{L}_V$ . It has the important property that  $f(\tau)$  is in  $\mathcal{L}_V$  means that there exists  $\hat{\tau}(\tau)$  and  $\tilde{f} \in \text{QDM}_{S^1}(V)$  such that

$$f = z M_V(\hat{\tau}(\tau), z) \tilde{f},$$

which can be seen as a Birkhoff factorization.

We now turn to  $\mathbb{P}(V)$ . There is a decomposition

$$H^*(\mathbb{P}(V)) = H^*(V)[p] / \prod_{\delta} (\delta + p),$$

where  $\delta$  runs over the Chern roots of  $V$ . This receives the Kirwan map

$$\kappa: H_{S^1}^*(V) \twoheadrightarrow H^*(\mathbb{P}(V)), \quad \kappa(\lambda) = p.$$

Thus the quantum  $D$ -module for  $\mathbb{P}(V)$  is

$$\text{QDM}(\mathbb{P}(V)) = H^*(\mathbb{P}(V)) \otimes \mathbb{C}[z, q][[Q, \hat{\tau}]],$$

where  $\hat{\tau} = \{\hat{\tau}_i\}$  is a basis for  $H^*(\mathbb{P}(V))$  and  $q$  is the Novikov variable of the fiber curve class. It is equipped with the connections  $\nabla_{\hat{\tau}_i}, \nabla_{\xi Q \partial_Q}, \nabla_{q \partial_q}, \nabla_{z \partial_z}$ .

*Remark 2.2.1.* Note there are no shift operators, but there is an additional  $q$ -direction in the quantum  $D$ -module for  $\mathbb{P}(V)$

We also have the symplectic space  $\mathcal{H}_{\mathbb{P}(V)}$ , the Lagrangian cone  $\mathcal{L}_{\mathbb{P}(V)}$ , and the fundamental solution  $M_{\mathbb{P}(V)}(\hat{\tau}, z)$ . Finally, we will recall the mirror theorem in the form that

$$I_{\mathbb{P}(V)} = \sum_{k \geq 0} \kappa(\mathcal{S}^{-k} J^{\lambda + kz}) q^k$$

lies on  $\mathcal{L}_{\mathbb{P}(V)}$ .

### 2.2.2 Discrete Fourier transform

**Definition 2.2.2.** The *discrete Fourier transform*  $\mathcal{H}_V \rightarrow \mathcal{H}_{\mathbb{P}(V)}$  is the transform

$$J^\lambda \mapsto \hat{J} = \sum_{k \geq 0} \kappa(\mathcal{S}^{-k} J^{\lambda + kz}) q^k.$$

In this framing, the mirror theorem states that the discrete Fourier transform of the  $J$ -function of  $V$  lies on the Lagrangian cone of  $\mathbb{P}(V)$ .

**Theorem 2.2.3.** *There exists a “mirror map”*

$$\hat{\tau} = \hat{\tau}(\tau) \in H^*(\mathbb{P}(V))[q][[Q, \tau]]$$

and an isomorphism

$$\text{FT}: \text{QDM}_{S^1}(V) \rightarrow \hat{\tau}^* \text{QDM}(\mathbb{P}(V))$$

of  $\mathbb{C}[z][[Q, \tau]]$ -modules intertwining the connections in the natural ways.

*Remark 2.2.4.* One has to be careful with the Novikov variables and think about approximately eight other points of the theorem, but we will ignore these for now.

Because the Fourier transform intertwines the connections, we have the commutative diagram

$$\begin{array}{ccc} \text{QDM}_{S^1}(V) & \xrightarrow{\text{FT}} & \tau^* \text{QDM}(\mathbb{P}(V)) \\ \downarrow M_V(\tau) & & \downarrow M_{\mathbb{P}(V)}(\hat{\tau}(\tau)) \\ \mathcal{H}_V & \xrightarrow{J \rightarrow \hat{J}} & \mathcal{H}_{\mathbb{P}(V)}. \end{array}$$

*Idea of proof.* The idea of the proof is to start from the mirror theorem (the bottom row) and apply Birkhoff factorization. The mirror theorem states that

$$(M_V(\tau)1)^\wedge = M(\hat{\tau}(\tau))Y \in \mathcal{L}_{\mathbb{P}(V)}$$

for some mirror map  $\hat{\tau}(\tau)$  and  $Y \in \text{QDM}(\mathbb{P}(V))$ . Using the intertwining properties of  $M$ , we see that

$$(M_V(\tau)(\phi_i \lambda^k))^\wedge = M(\hat{\tau}(\tau)) z \tau^* \nabla_{\frac{\partial}{\partial t^{i,k}}} Y.$$

Defining

$$\text{FT}(\phi_i \lambda^k) := z \tau^* \nabla_{\partial_{\tau^{i,k}}} Y$$

and  $\hat{\tau}$  to be the mirror map appearing in the Birkhoff factorization, we are done.  $\square$

*Remark 2.2.5.* The mirror map satisfies

$$\widehat{\tau}(\tau)|_{q=Q=0} = \kappa(\tau)$$

and the Fourier transform satisfies

$$\text{FT}(\phi_i \lambda^k)|_{Q=\tau=0} = \phi_i p^k.$$

*Remark 2.2.6.* The Fourier transform intertwines the natural pairings on the quantum  $D$ -modules.

### 2.2.3 Continuous Fourier transform

**Definition 2.2.7.** Define

$$\text{QDM}(\mathbb{P}(V))_{\text{loc}} := \text{QDM}(\mathbb{P}(V)) \otimes \mathbb{C}[z] \langle q^{-\frac{1}{r'}} \llbracket Q, \widehat{\tau} \rrbracket, \rangle$$

where  $r' = r$  or  $2r$  depending on parity.

**Theorem 2.2.8.** For  $j = 0, \dots, r-1$ , there exist maps  $H^*(\mathbb{P}(V)) \rightarrow H^*(B)$  given by

$$\widehat{\tau} \mapsto \zeta_j(\widehat{\tau}) \in -c_1(V) \log \left( e^{\frac{2\pi\sqrt{-1}j}{r}} q^{\frac{1}{r}} \right) + H^*(B) \langle q^{-\frac{1}{r}} \llbracket Q, \widehat{\tau} \rrbracket \rangle$$

and an isomorphism

$$\Phi: \text{QDM}(\mathbb{P}(V))_{\text{loc}} \cong \bigoplus_{j=0}^{r-1} \zeta_j^* \text{QDM}(B)_{\text{loc}}$$

intertwining the pairings and quantum connections in a natural way, namely that

$$\Phi \Delta = \bigoplus \zeta_j^* \Delta \Phi.$$

Writing  $\Phi = (\Phi_0, \dots, \Phi_j)$ , we have

$$\Phi_j(\phi_i p^k)|_{Q=\widehat{\tau}=0} = \frac{1}{\sqrt{r}} \lambda_j^{k-\frac{r-1}{2}} (\phi_i + O(q^{-\frac{1}{r}})).$$

*Idea of proof.* We use another realization of the Fourier transform on  $\text{QDM}_{S^1}(V)$  and

$$\text{FT}: \text{QDM}_{S^1} \cong \widehat{\tau}^* \text{QDM}(\mathbb{P}(V)).$$

If we consider  $\Delta_V^\lambda$  arising from Quantum Riemann-Roch, it is given as

$$\Delta_V^\lambda \asymp \prod_{\rho} \sqrt{\frac{z}{2\pi}} z^{\frac{\lambda+\rho}{z}} \Gamma\left(\frac{\rho+\lambda}{z} + 1\right).$$

Shifting by  $-z$ , we see that

$$\Delta_V^{\lambda-z} = \Delta_V^\lambda \prod_{\rho} \frac{1}{\rho + \lambda} = \Delta_V^\lambda \frac{1}{e_{S^1}(V)}.$$

We now consider the transformation

$$s \mapsto \int q^{\frac{\lambda}{z}} (\Delta_V^\lambda)^{-1} M_V(\tau) \cdot s \, d\lambda$$

for  $s \in \text{QDM}_{\text{SI}}(V)$ . Because this integral intertwines  $\mathbb{S}$  with  $q$  and  $\lambda$  with  $z\nabla_{q\partial_q}$ , it formally gives a solution to  $\text{QDM}(\mathbb{P}(V))$ .

To make sense of this terrible expression, we use the stationary phase expansion of the integral. Setting

$$I(s) = \int e^{-\frac{\varphi(\lambda)}{z}} \lambda^{-\frac{c_1(V)}{z}} \lambda^{-\frac{r}{2}} (\tilde{\Delta}_V^\lambda)^{-1} J^\lambda d\lambda,$$

where  $\frac{\varphi(\lambda)}{z}$  is the Stirling asymptotics of  $\Delta_V^\lambda$ , given by

$$\varphi(\lambda) = r(\lambda \log \lambda - \lambda) - \lambda \log q.$$

The critical points of  $\varphi$  are given by

$$\frac{\partial}{\partial \lambda} \varphi(\lambda) = r(\log \lambda) - \log q = 0,$$

which tells us that  $\lambda^r = q$ . Thus, we obtain  $r$  solutions

$$\lambda_j = e^{\frac{2\pi\sqrt{-1}j}{r}} q^{\frac{1}{r}}.$$

We now consider the formal expansions around  $\lambda_j$ . These produce a “continuous Fourier transform”

$$J \mapsto \mathcal{F}_j(J)$$

such that

$$I(M^{-1}J) \asymp \sqrt{2\pi z} e^{r\frac{\lambda_j}{z}} \mathcal{F}_j(J).$$

These intertwine the quantum connection and multiplication by  $\lambda$ , as in

$$\begin{aligned} \mathcal{F}_j(\lambda J) &= (\lambda_j + zq\partial_q)\mathcal{F}_j(J) \\ \mathcal{F}_j(\mathbb{S}J) &= q\mathcal{F}_j(J), \end{aligned}$$

so  $z\mathcal{F}_j(J_V(\tau))$  is on the Lagrangian cone of  $B$ . We then use the following result:

**Proposition 2.2.9.** *We have*

$$\mathcal{F}_j(J_V(\tau)) = M_B(\sigma_j(\tau))v_j$$

for some  $\sigma_j, v_j$ .

Unfortunately,  $\mathcal{F}_j$  does not intertwine  $\nabla_{z\partial_z}$  correctly. To fix this, define

$$\zeta_j(\hat{\tau}) = \sigma_j(\tau(\hat{\tau})) + r\lambda_j$$

and  $\Phi_j$  by a shift of  $v_j$ . □

#### 2.2.4 Discrete equals continuous

**Warning 2.2.10.** **Everything in this subsection may be false.**

Consider the Fourier transform

$$\int \prod_{\rho} \Gamma\left(-\frac{\rho + \lambda}{z}\right) J_V^\lambda q^{\frac{\lambda}{z}} d\lambda.$$

This can be computed either using residues or using stationary phase asymptotics. Using residues, we obtain

$$\sum_{k \geq 0} \operatorname{Res}_{p=0} \Gamma\left(-k - \frac{\rho + \lambda}{z}\right) J_V^{\lambda + kz} q^{\frac{p}{z}} q^k,$$

which is precisely

$$\frac{1}{\prod_{c=0}^k e_{p+\lambda z}(V)} \Gamma\left(-\frac{\rho + \lambda}{z}\right).$$

Using stationary phase asymptotics, we obtain the  $I(s)$  defined previously.

## Quantum cohomology of blowups

### 3.1 Setup (Kostya, Mar 07)

Let  $X$  be a smooth projective variety,  $Z \subset X$  be a smooth closed subvariety of codimension  $r$ , and

$$\varphi: \tilde{X} = \text{Bl}_Z X \rightarrow X$$

be the blowup of  $X$  with center  $Z$ . Denote the exceptional divisor by

$$j := D \cong \mathbb{P}(N_{Z/X}) \hookrightarrow \tilde{X}.$$

As a vector space, there is an isomorphism

$$H^*(X) = H^*(X) \oplus \bigoplus_{i=0}^{r-2} H^*(Z).$$

Our goal is to upgrade this to the level of quantum cohomology. However, this is very tricky because of convergence issues, so it will be a corollary of a decomposition theorem for quantum  $D$ -modules.

Recall that the quantum  $D$ -module of  $X$  is given by

$$\text{QDM}(X) = H^*(X)[z][[Q, \tau]]$$

with the Dubrovin connection

$$\nabla_{\partial_\tau}, \nabla_{\xi_Q \partial_Q}, \nabla_{z \partial_z}$$

and pairing

$$(f(z), g(z)) = \int_X f(-z)g(z).$$

**3.1.1 Statement of the theorem** The first problem we need to fix is that the cohomological and Novikov variables of  $X, Z, \tilde{X}$  are different.

**Definition 3.1.1.** The *extended Novikov ring* is defined as

$$\mathbb{C}[[Q]] := \mathbb{C}[[Q, xy^{-1}, Q^{\varphi_* \tilde{d}} y^{-[D] \cdot \tilde{d}}]],$$

where  $d \in \text{NE}_{\mathbb{N}}(X)$  and  $\tilde{d} \in \text{NE}_{\mathbb{N}}(\tilde{X})$ .

Introducing another formal variable  $q$ , we can embed the Novikov rings of  $Z, X, \tilde{X}$  into  $\mathbb{C}[[q^{-\frac{1}{s}}]][[Q]]$ , where  $s$  is either  $r-1$  or  $2(r-1)$  depending on the parity of  $r$  (we want  $s$  to be even):

- $\mathbb{C}[[Q]]$  embeds as  $Q^d \mapsto Q^d$ ;
- $\mathbb{C}[[\tilde{Q}]]$  embeds as  $\tilde{Q}^{\tilde{d}} \mapsto Q^{\varphi_* \tilde{d}} q^{-[D] \cdot \tilde{d}}$ ;
- $\mathbb{C}[[Q_Z]]$  embeds as  $Q_Z^d \mapsto Q^{\iota_* d} q^{-\frac{\rho_Z \cdot d}{r-1}}$ , where  $\rho_Z = c_1(N_{Z/X})$ .

Later, we will see that  $q = yS^{-1}$ , where  $S^{-1}$  will be an equivariant variable for a  $\mathbb{C}^*$  action. Denote

$$\mathrm{QDM}(X)^{\mathrm{La}} := \mathrm{QDM}(X) \otimes_{\mathbb{C}[[Q]]} \mathbb{C}[[Q]].$$

We can now state the main result.

**Theorem 3.1.2.** *There exists a formal invertible change of variables*

$$H^*(\tilde{X}) \rightarrow H^*(X) \oplus H^*(Z)^{\oplus r-1}$$

denoted by

$$\tilde{\tau} \rightarrow \left( \tau(\tilde{\tau}), \{\zeta_j(\tilde{\tau})\}_{j=0}^{r-2} \right)$$

and an isomorphism

$$\Psi: \mathrm{QDM}^{\mathrm{La}}(\tilde{X}) \xrightarrow{\cong} \tau^* \mathrm{QDM}(X)^{\mathrm{La}} \oplus \bigoplus_{j=0}^{r-2} \zeta_j^* \mathrm{QDM}(Z)^{\mathrm{La}}$$

such that  $\Psi$  intertwines the quantum connections and the pairings.

### 3.1.2 The master space

**Definition 3.1.3.** Define the *master space*

$$W := \mathrm{Bl}_{Z \times \{0\}} X \times \mathbb{P}^1 \xrightarrow{\hat{\varphi}} X \times \mathbb{P}^1$$

to be the degeneration to the normal cone of  $Z \subset X$ . This is endowed with a  $T = \mathbb{C}^\times$ -action extending the action

$$\lambda \cdot (x, u) = (x, \lambda u)$$

for  $(x, u) \in X \times \mathbb{P}^1$ . See Figure 3.1 for a picture of  $W$ .

The fixed locus of the  $\mathbb{C}^*$ -action is given by

$$W^{\mathbb{C}^*} = X \sqcup \tilde{X} \sqcup Z.$$

We can also see that

$$\begin{aligned} N_T^1(W) &= \hat{\varphi}^* N_T^1(X \times \mathbb{P}^1) \oplus \mathbb{Z}[\tilde{D}] \\ &\cong N^1(X) \oplus \mathbb{Z}^3 \ni (\omega, t, \varepsilon, a). \end{aligned}$$

Note here that

$$N_T^1(X \times \mathbb{P}^1) = \mathrm{pr}_1^* N^1(X) \oplus \mathbb{Z}[X] \oplus \mathbb{Z}\lambda,$$

Figure 3.1:  $W = \text{Bl}_{Z \times \{0\}}(X \times \mathbb{P}^1)$  and a moment map  $\mu: W \rightarrow \mathbb{R}$

so a general class in  $N_1^T(W)$  can be written as

$$\hat{\varphi}^* \text{pr}_1^* \omega + t[X] - \epsilon[\hat{D}] + a \cdot \lambda.$$

The dual notion is the group of 1-cycles, which is given by

$$N_1^T(W) \cong N_1(X) \oplus \mathbb{Z}^3 \ni (d, k, \ell, m) =: \beta,$$

whose Novikov variable is

$$Q^d x^k y^\ell S^m.$$

Note that

$$[X] \cdot \beta = k, \quad -[\hat{D}] \cdot \beta = \ell.$$

The effective curve classes are those which are equivariant, so they either lie in the fixed loci or are 1-dimensional orbits. There are classes  $C_1$  lying entirely inside  $X$ , classes  $C_2$ , which are  $x \times \mathbb{P}^1$  for  $x \notin Z$ , classes  $C_3 \subset Z \times \mathbb{P}^1$ , and classes  $C_4 \subset \hat{D}$ . The corresponding Novikov variables are  $Q^d, x, xy^{-1}$ , and  $y$ , respectively.

**Lemma 3.1.4.** *The monoid of effective curve classes is generated by  $C_1, C_2, C_3, C_4, S$ .*

**Example 3.1.5.** Let  $X = \mathbb{P}^1 \times \mathbb{P}^1$  and  $Z = (0, 0)$ . Then a toric diagram for  $W$  with  $C_1, C_2, C_3, C_4$  is given in Figure 3.2.

The  $T$ -ample cone  $C_T(W)$  of  $W$  is the dual to the cone of effective curve classes. Then  $\hat{\omega} \in C_T(W)$  if the set of  $\hat{\omega}$ -stable points under the  $\mathbb{C}^*$ -action is nonempty. Then there is a decomposition

$$\overline{C_T(W)} = \overline{C_X} \cup \overline{C_{\tilde{X}}}$$

into pieces where the GIT quotient

$$W //_{\hat{\omega}} T \cong X \text{ or } \tilde{X},$$

respectively. The stable points are

- For  $\hat{\omega} \in C_X$ , the stable points are  $X \times \mathbb{C}^*$ ;
- For  $\hat{\omega} \in C_{\tilde{X}}$ , the stable points are  $\mathcal{O}_{\tilde{X}}(-\hat{D}) \setminus \hat{X}$ .

Figure 3.2: Toric diagram of  $W$  for  $X = \mathbb{P}^1 \times \mathbb{P}^1$  and  $Z = (0,0)$  with curve classes  $C_1, C_2, C_3, C_4$ .

Figure 3.3: A schematic picture of the cones  $C_X^\vee$  and  $C_{\tilde{X}}^\vee$  in  $N_1^T(W)$ .

The dual cones  $C_X^\vee$  and  $C_{\tilde{X}}^\vee$  correspond to embeddings of the effective cones of  $X$  and  $\tilde{X}$ , respectively, into the effective cone of  $W$  as in Figure 3.3.

Recall the *Kirwan map*

$$\begin{aligned} \kappa_Y: H_T^*(W) &\twoheadrightarrow H_T^*(W^s) = H^*(Y) \\ \kappa_Y^*: \text{NE}_N(Y) &\rightarrow N_1^T(W), \end{aligned}$$

where  $Y$  is either  $X$  or  $\tilde{X}$ .

Now consider the equivariant quantum  $D$ -module

$$QDM_T(W) = H_T^*(W)[z][[\hbar, \theta]]$$

endowed with the quantum connection and the action of the shift operators

$$\hat{S}_\beta(\theta), \quad \beta \in N_1^T(W) \cong N_1(X) \oplus \mathbb{Z}^3,$$

which are defined by

$$\widehat{S}^\beta(\theta) = Q^d x^k y^\ell S(\theta)^m,$$

where  $\beta$  is identified with  $(d, k, \ell, m)$  under the factorization  $N_1(X) \oplus \mathbb{Z}^3$ .

We can obtain the quantum  $D$ -modules for  $X$  and  $\tilde{X}$  from the equivariant quantum  $D$ -module of  $W$  by taking affine charts and completing. Here, we think of  $\text{QDM}_T(W)$  as a global Kähler moduli space.

Figure 3.4: Global Kähler moduli space associated with  $\text{QDM}_T(W)$ . See also Figure 3.3.

**3.1.3 Fourier transforms** To construct the map in Theorem 3.1.2, Iritani uses both the discrete and continuous Fourier transforms. For  $f \in \mathcal{H}_W$ , the discrete Fourier transform is given by

$$F_Y(f) := \sum_{k \in \mathbb{Z}} S^k \kappa_Y(S^{-k} f) \in \mathcal{H}_Y^{\text{ext}}.$$

The continuous Fourier transform for  $Z \in \pi_0(W^T)$  is given by sending  $f \in \mathcal{H}_W$  to the element of  $\mathcal{H}_Z$  given by the formal asymptotic expansion of

$$\int e^{\lambda \log \frac{s}{z}} \Delta_Z^{-1} f|_Z d\lambda.$$

*Remark 3.1.6.* We can think of  $X$  and  $\tilde{X}$  either as fixed components  $X, \tilde{X} \in \pi_0(W^T)$  (corresponding to the continuous Fourier transform) or as GIT quotients  $W //_{\widehat{\omega}} T$ , corresponding to the discrete Fourier transform. These are in fact equal up to a factor.

Note that  $Z$  is not a GIT quotient of  $W$ , but is a fixed component, so there is a continuous Fourier transform to  $W$ . In total, we have three morphisms

$$\begin{array}{ccc} & & \text{QDM}(\tilde{X}) \\ & \nearrow \cong & \\ \text{QDM}_T(W) & \longrightarrow & \text{QDM}(X) \\ & \searrow r-1 & \\ & & \text{QDM}(Z). \end{array}$$

### 3.2 Fourier analysis for blowups (Sam, Mar 21)

In this section, denote the Chern roots of  $\mathcal{N}_{Z/X}$  by  $\varepsilon_1, \dots, \varepsilon_r$ .

**3.2.1 Extended Kirwan maps** We will begin by describing the Kirwan maps in coordinates. On  $H_T^2(W)$ , we have

$$\begin{aligned} \kappa_X: \widehat{\varphi}^* \mathrm{pr}_1^* \alpha &\mapsto \alpha \\ [X] &\mapsto 0 \\ -[\widehat{D}] &\mapsto 0 \\ \lambda &\mapsto 0 \end{aligned}$$

for  $Y = X$

$$\begin{aligned} \kappa_{\widetilde{X}}: \widehat{\varphi}^* \mathrm{pr}_1^* \alpha &\mapsto \varphi^* \alpha \\ [X] &\mapsto 0 \\ -[\widehat{D}] &\mapsto -[D] \\ \lambda &\mapsto [D] \end{aligned}$$

for  $Y = \widetilde{X}$ . The dual Kirwan maps on  $N_1(Y)$  are given by

$$\begin{aligned} \kappa_X^*: N_1(X) &\rightarrow N_1^T(W) \cong N_1(X) \oplus \mathbb{Z}\lambda^\vee \oplus \mathbb{Z}[X]^\vee \oplus \mathbb{Z}(-[\widehat{D}])^\vee \\ d &\mapsto (d, 0, 0, 0) \\ \kappa_{\widetilde{X}}^*: N_1(\widetilde{X}) &\rightarrow N_1^T(W) \cong N_1(X) \oplus \mathbb{Z}\lambda^\vee \oplus \mathbb{Z}[X]^\vee \oplus \mathbb{Z}(-[\widehat{D}])^\vee \\ \widetilde{d} &\mapsto (\varphi_* \widetilde{d}, 0, -[D] \cdot \widetilde{d}, [D] \cdot \widetilde{d}) \end{aligned}$$

when  $Y = X$  and  $Y = \widetilde{X}$ , respectively. It may appear that we don't see the equivariant parameters in the dual Kirwan map, but we will fix this.

**Definition 3.2.1.** The *extended Givental space* is

$$\mathcal{H}_Y^{\mathrm{ext}} := H^*(Y)[z^\pm][\mathbb{C}_{Y,N}^\vee],$$

which is a base change of  $\mathcal{H}_Y$ .

The shift operators on  $\mathcal{H}_W^{\mathrm{rat}} = H_{\mathrm{loc}}^*(W)[Z^\pm][Q]$  are now given by

$$\mathcal{S}t_*(f_X, f_Z, f_{\widetilde{X}}) = (\mathcal{S}f|_X, \mathcal{S}f|_Z, \mathcal{S}f|_{\widetilde{X}}),$$

where

$$\begin{aligned} \mathcal{S}^k f_X &= x^k \frac{\prod_{c=-\infty}^0 (-\lambda + cz)}{\prod_{c=-\infty}^k (-\lambda + cz)} e^{-kz\partial_\lambda} f_X \\ \mathcal{S}^k f_Z &= y^k \frac{\prod_{c=-\infty}^0 \prod_{i=1}^r (\varepsilon_i - \lambda + cz) \prod_{c=-\infty}^0 (\lambda + cz)}{\prod_{c=-\infty}^k \prod_{i=1}^r (\varepsilon_i - \lambda + cz) \prod_{c=-\infty}^k (\lambda + cz)} e^{-kz\partial_\lambda} f_Z \\ \mathcal{S}^k f_{\widetilde{X}} &= \frac{\prod_{c=-\infty}^0 ([D] + \lambda + cz)}{\prod_{c=-\infty}^k ([D] + \lambda + cz)} e^{-kz\partial_\lambda} f_{\widetilde{X}}. \end{aligned}$$

**3.2.2 Discrete Fourier transform** We are now able to make the following definition.

**Definition 3.2.2.** The *discrete Fourier transform* is

$$F_Y: \mathcal{H}_W^{\text{rat}}[Q^{-1}] \dashrightarrow \mathcal{H}_Y^{\text{ext}}[Q^{-1}],$$

defined by

$$F_Y(f) = \sum_{k \in \mathbb{Z}} S^k \kappa_Y(S^{-k} f).$$

Because we invert the equivariant parameters, this may not necessarily be well-defined. However, we do have the following result.

**Proposition 3.2.3.** *The discrete Fourier transform  $F_Y$  is well-defined on tangent spaces to  $\mathcal{L}_W$ .*

To prove this result, we need various ingredients:

1. Some regularity at  $\lambda = 0$ , which follows from properness;
2. Not needing arbitrarily high powers of  $Q^{-1}$  (landing in the target).

As in the case of projective bundles, the shift operators satisfy various nice properties. For example, because

$$[\lambda, S^k] = z^k S,$$

we obtain the formulae

$$\begin{aligned} F_Y(S^\ell f) &= S^\ell F_Y(f) \\ F_Y(\xi f) &= (z\xi Q \partial_Q + \kappa_Y(\xi)) F_Y(f) \end{aligned}$$

for any  $\xi \in H_2^T(W)$ .

**3.2.3 Continuous Fourier transform** Let  $F \in \{X, \tilde{X}, Z\}$  be a fixed component in  $W^T$ . Denote the Chern roots of  $\mathcal{N}_{F/W}$  by  $\rho_1, \dots, \rho_n$ . Now define

$$G_F := \prod_{\rho} \frac{1}{\sqrt{-2\pi z}} (-z)^{-\frac{\rho}{z}} \Gamma\left(\frac{-\rho}{z}\right).$$

More specifically, for each individual fixed component, we have

$$\begin{aligned} G_X &= \frac{1}{-2\pi z} (-z)^{\frac{\lambda}{z}} \Gamma\left(\frac{\lambda}{z}\right) \\ G_Z &= \frac{1}{\sqrt{-2\pi z}^{r+1}} (-z)^{-\frac{\lambda}{z}} \Gamma\left(\frac{-\lambda}{z}\right) \prod_{i=1}^r (-z)^{\frac{\lambda - \varepsilon_i}{z}} \Gamma\left(\frac{\lambda - \varepsilon_i}{z}\right) \\ G_{\tilde{X}} &= \frac{1}{\sqrt{-2\pi z}} (z)^{\frac{[D] - \lambda}{z}} \Gamma\left(\frac{[D] - \lambda}{z}\right). \end{aligned}$$

This  $G_F$  actually intertwines all  $\widehat{S}^\beta$ , which are defined for all

$$\beta \in N_1^T(W) \rightarrow H_2(BT) \ni \bar{\beta}.$$

Given  $F$ , we have

$$\sigma_k(F) \in N_1(E_k) \rightarrow N_1^T(W),$$

Figure 3.5: Toric diagram of  $E_k$  when  $X, Z$  are as in Figure 3.2.

which are obtained by section classes on  $E_k$  as in Figure 3.5. Now  $G_F$  satisfies the equation

$$G_F(\widehat{\mathcal{S}}^\beta f)_F = (Q^{\beta + \sigma_F(-\bar{\beta})} e^{-z\bar{\beta}\partial_\lambda}) G_F f,$$

which follows from the same argument as in the projective bundle case.

We are now able to describe the continuous Fourier transform formally as an integral which has the same properties as the discrete one. Define

$$\mathcal{FT}^\infty: f \mapsto \int e^{\lambda \log \frac{S_f}{z}} G_F f_F d\lambda,$$

where  $S_F = \sigma_1(F)$ . Formally, we see that

$$\begin{aligned} \mathcal{FT}^\infty(\widehat{\mathcal{S}}^\beta f) &= \int e^{\lambda \log \frac{S_F}{z}} Q^{\beta + \sigma_1(-\bar{\beta})} e^{z\bar{\beta} \log \frac{S_F}{z}} G_F f_F d\lambda \\ &= \widehat{\mathcal{S}}^\beta \mathcal{FT}^\infty(f), \end{aligned}$$

which suggests that this is the right object to study the asymptotics of. Recall the Stirling approximation

$$\begin{aligned} \log G_F &\asymp \sum_{\rho_i} -\frac{\rho_i \log \rho_i - \rho_i}{z} - \frac{1}{2} \log \rho_i - \sum_{n=2}^{\infty} \frac{B_n}{n(n-1)} \left(\frac{z}{\rho_i}\right)^{n-1}, \\ &= \sum_{\alpha \in \text{wts}(\mathcal{N}_{F/W})} \left( -r_\alpha \frac{\alpha \log \alpha - \alpha}{z} - \log \Delta_\alpha \right), \end{aligned}$$

where we have the decomposition

$$\mathcal{N}_{F/W} = \bigoplus_{\alpha} \mathcal{N}^\alpha,$$

$\rho_\alpha = c_1(\mathcal{N}^\alpha)$  is the first Chern class,  $r_\alpha = \text{rk } \mathcal{N}^\alpha$ , and  $\Delta_\alpha$  is the quantum Riemann-Roch operator. We now obtain

$$\mathcal{FT}^\infty \asymp \int e^{\frac{\lambda \log S_F - \sum_{\alpha} r_{\alpha} (\alpha \log \alpha - \alpha)}{z}} \prod_{\alpha} \Delta_{\alpha}^{-1} f_F d\lambda.$$

We have a critical point

$$\lambda_0 = S_F^{\frac{1}{c}} \prod_{\alpha} w_{\alpha}^{-r_{\alpha} \frac{w_{\alpha}}{c_F}},$$

where

$$c_F = \begin{cases} -1 & F = X \\ 1 & F = \tilde{X} \\ -(r-1) & F = Z. \end{cases}$$

Also, for  $j = 0, \dots, |c_F| - 1$ , we have critical points

$$\lambda_j = e^{\frac{2\pi\sqrt{-1}j}{c_F}} \lambda_0.$$

**Definition 3.2.4.** The *continuous Fourier transform* is given by the asymptotic expansion

$$\int e^{\lambda \log \frac{S_F}{z}} G_F f_F d\lambda \asymp \sqrt{2\pi z} e^{r \frac{\lambda_j}{z}} \mathcal{F}_{F,j}(f),$$

where we take the asymptotics as  $z \rightarrow 0$  and substitute

$$\lambda = \lambda_j \exp\left(\frac{u}{\sqrt{c\lambda_j}}\right)$$

and expand in  $u$ -powers as  $u \rightarrow 0$ .

Via taking a formal asymptotic analysis of what we did before, we have

**Proposition 3.2.5.**

1. The continuous Fourier transform intertwines the shift operators as

$$\mathcal{F}_{F,j}(\widehat{S}^{\beta} f) = \widehat{S}^{\beta} \mathcal{F}_{F,j}(f);$$

2. The continuous Fourier transform intertwines the equivariant parameter via

$$\mathcal{F}_{F,j}(\lambda f) = (zS + \lambda_j) \mathcal{F}_{F,j}(f).$$

3. There is a similar property for the Euler vector field.

Now let

$$\widehat{J}_{F,j}^{\text{tw}} = \mathcal{F}_{F,j}(\iota_* J_F^{\text{tw}}(t)).$$

**Proposition 3.2.6.** *There exists*

$$\tau(t) \in H^*(F) \llbracket S_F^{-\frac{1}{c}}, Q_F S^{-\frac{\rho_F}{c}}, t S_F^{\frac{*}{c}} \rrbracket$$

and

$$v(t) \in H^*(F)[z] \llbracket S_F^{-\frac{1}{c}}, Q_F S^{-\frac{\rho_F}{c}}, t S_F^{\frac{*}{c}} \rrbracket$$

such that

$$\widehat{J}_{F,j}^{\text{tw}} = S_F^{-\frac{\rho_F}{cz}} M_F(\tau(t) Q_F S_F^{-\frac{\rho_F}{cz}}) v.$$

In other words, we can recover  $\text{QDM}_F$  from  $\mathcal{F}_{F,j}$  after a change of basis and an étale cover of the Kähler moduli space.

**Proposition 3.2.7.** *The discrete and continuous Fourier transforms agree for  $Y \in \{X, \tilde{X}\}$ . In other words, we have*

$$e^{S_Y^{\frac{1}{c_Y}}} \mathcal{F}_{Y,0}(f) = c_Y^{-1} S_Y^{-\frac{\rho_Y}{c_Y^2}} F_Y(f).$$

### 3.3 Decomposition (Sam, Mar 28)

**3.3.1 A general picture** We begin by stating some general conjectures that the blowup result fits into.

**Conjecture 3.3.1** (Dubrovin). *Let  $X$  be smooth and projective. If there exists a semiorthogonal decomposition*

$$D^b(X) = \langle D^b(X_1), \dots, D^b(X_n) \rangle,$$

*then there is a decomposition*

$$\mathrm{QDM}(X) = \bigoplus_i \mathrm{QDM}(X_i).$$

*More specifically, if  $X$  admits a full exceptional collection,  $\mathrm{QDM}(X)$  can be extended to  $\mathcal{O}^{\mathrm{an}}[[z]]$ . In addition the Gram matrix of the pairing  $\chi(-, -)$  on  $K(X)$  is recovered as the Stokes matrix*

$$S = \Phi_{\arg z \in (-\pi, 0+\varepsilon)} \Phi_{\arg z \in (0, \pi)}^{-1}$$

*of flat sections of the irregular connection*

$$z \partial_z + \frac{1}{z} E_X \star_\tau + \mu_X.$$

On the level of derived categories, we have a decomposition

$$D^b(\tilde{X}) = \langle D^b(X), D^b(Z)_0, \dots, D^b(Z)_{r-2} \rangle,$$

so we expect a decomposition

$$\mathrm{QDM}(\tilde{X}) = \bigoplus_{\mu \in \mathrm{Spec}(E_{\tilde{X}} \star_\tau)} \mathrm{QDM}(\tilde{X})_\mu.$$

In the limit  $Q\tau \rightarrow 0$ , we obtain  $\mathrm{QDM}(X)$  at  $\mu = 0$  and  $r - 1$  copies of  $\mathrm{QDM}(Z)$  at roots of unity. The shift away from  $\mu = 0$  will correspond to the shift of saddle points in the Fourier transform.

In the equivariant setting, we have semiorthogonal decompositions

$$D_T^b(W) = \langle D^b(W //_\theta T), \dots \rangle.$$

We then expect

**Conjecture 3.3.2.** *Setting  $W //_\theta T =: Y$ , then*

$$I := \sum_{\beta} \kappa_Y(\hat{S}^{-\beta} J_W(\tau)) \hat{S}^{\beta}$$

*lies on the Lagrangian cone of  $Y$ .*

**3.3.2 Decomposition of the quantum  $D$ -module** First, we would like to give a more precise formulae for the quantities appearing in Proposition 3.2.6. First,  $\tau$  is given by

$$\tau|_{Q=0} = h_{F,j} + \dots,$$

where

$$h_{F,j} = 2\pi i j \frac{c_1(N_{F/W})}{c_F} + \sum_{\alpha} \left( \text{rk}_{\alpha} w_{\alpha} \frac{c_1(N_{F/W})}{c_F} - c_1(N_{F/W}^{\alpha}) \right).$$

Then we have

$$v|_{Q=0} = q_{F,j}(1 + \cdots),$$

where

$$q_{F,j} = \sqrt{c_F^{-1} \lambda_j} \prod_{\alpha} (w_{\alpha \lambda_j})^{\frac{\text{rk}_{\alpha}}{2}}$$

for  $\lambda_j = e^{\frac{1\pi i j}{c_F}} \lambda_0$ .

For  $X, \tilde{X}$ , the continuous Fourier transform  $\mathcal{F}_{F,j}$  intertwines  $S^{\beta}$  and  $\lambda$  with  $\xi S \frac{\partial}{\partial S}$  and  $E_W^T \star_{\tau} + \mu_W$  with  $E_{\tilde{X}} \star_{\tau} + \mu_X + \frac{1}{2}$ . On the other hand, for  $F = Z$ , the critical points are different, so there is a shift in  $\lambda$ . For example, we have

$$\mathcal{F}_{F,j}(\lambda f) = \left( z S \frac{\partial}{\partial S} + \lambda_j \right) \mathcal{F}_{F,j}(f)$$

because the integral satisfies the formula

$$z S \frac{\partial}{\partial S} \int e^{\log \frac{S}{z} (\lambda - \lambda_j)} f G d\lambda = \int (\lambda - \lambda_j) e^{\log \frac{S}{z} (\lambda - \lambda_j)} f G d\lambda.$$

A similar argument yields

$$\mathcal{F}_{F,j} \left( \left( z \partial_z + \mu_Z + \frac{1}{2} \right) f \right) = (z \partial_z + z^{-1} (c_1(F) + c_F \lambda_j + \mu_F)) \mathcal{F}_{F,j}(f).$$

We next need a space on which to compare  $\text{QDM}(X)$ ,  $\text{QDM}(\tilde{X})$ , and  $\text{QDM}_T(W)$  via the dual Kirwan maps. Define

$$\text{QDM}(Y)^{\text{ext}} := \text{QDM}(Y) \otimes \mathbb{C}[[C_{Y,\mathbb{N}}^{\vee}]]$$

and extend  $\nabla$  trivially on  $C_{Y,\mathbb{N}}^{\vee}$ . As in Figure 3.4, we have  $\mathfrak{M}_{\tilde{X}}$  and  $\mathfrak{M}_X$ , but we also need

$$\mathfrak{M}_0 = \text{Spf } \mathbb{C}[z][[\text{NE}_{\mathbb{N}}^T(W)]]\llbracket \theta \rrbracket.$$

The three charts can be compared on the chart

$$\mathfrak{U} = \text{Spf } \mathbb{C}[z][[\text{NE}_{\mathbb{N}}^T(W)]]\llbracket \theta \rrbracket \langle q^{-\frac{1}{s}} \rangle.$$

The comparison of the effective cones of curves is given in Figure 3.3.

The comparison also requires a completion and localization of  $\text{QDM}_T(W)$ . In order to compare with  $\text{QDM}(\tilde{X})$  we need the action of extended shift operators  $S^{\beta}$ . Define

$$\text{QDM}_T(W)_{\tilde{X}} := \mathbb{C}[C_{\tilde{X},\mathbb{N}}^{\vee}] \cdot \text{QDM}_T(W) \subset \text{QDM}_T(W)(Q^{-1}).$$

The completion is given by

$$\widehat{\text{QDM}_T(W)}_{\tilde{X}} = \text{QDM}_T(W)\llbracket S, yS^{-1} \rrbracket.$$

Now let

$$\begin{aligned}\tau(\theta) &= xS + \cdots \\ v(\theta) &= 1 + \cdots \\ \tilde{\tau}(\theta) &= S + \cdots \\ \tilde{v}(\theta) &= 1 + \cdots\end{aligned}$$

such that

$$\begin{aligned}F_X(J_w(\theta)) &= M_X(\tau(\theta))v(\theta) \\ F_{\tilde{X}}(J_w(\theta)) &= M_{\tilde{X}}(\tilde{\tau}(\theta))\tilde{v}(\theta).\end{aligned}$$

By taking derivatives  $\partial_{\theta^{ik}}$ , the Fourier transform is lifted to a map of quantum  $D$ -modules.

**Theorem 3.3.3.** *There is an isomorphism*

$$\widehat{\text{FT}}_{\tilde{X}}: \widehat{\text{QDM}}_T(W)_{\tilde{X}} \rightarrow \tilde{\tau}^* \text{QDM}(\tilde{X})^{\text{ext}}$$

and a projection

$$\widehat{\text{FT}}_X: \widehat{\text{QDM}}_T(W)_{\tilde{X}} \rightarrow \tau^* \text{QDM}(X)^{\text{ext}}.$$

They intertwine the quantum connection and the pairing up to a  $\frac{1}{2}$  shift in  $\mu$ .

These extend to the completions, but we will not prove this here.

For  $F = Z$  and any  $j$ , there are coordinates

$$\begin{aligned}\sigma_j(\theta) &= h_{Z,j} + \cdots \\ u_j(\theta) &= q_{Z,j} + \cdots\end{aligned}$$

such that

$$q^{\frac{c_1(N_Z/W)}{(r-1)z}} \mathcal{F}_{Z,j}(J_w(\theta)) = M(\sigma_j(\theta))u_j(\theta).$$

**Theorem 3.3.4.** *There are projections*

$$\widehat{\text{FT}}_{Z,j}: \widehat{\text{QDM}}_T(W)_{\tilde{X}} \rightarrow \sigma_j^* \text{QDM}(Z)^{\text{ext,loc}}$$

which intertwine  $\lambda$  with  $z\nabla_{S\partial_S} + \lambda_j$  and  $z\nabla_{\xi Q\partial_Z}$  with  $z\nabla_{\widehat{S}\partial_{\widehat{S}}} + \iota_{\text{pt}}^* \xi|_{\lambda=\lambda_i}$ . Here,  $\text{QDM}(Z)^{\text{ext,loc}}$  is defined by the extension

$$\mathbb{C}[z][Q_Z, \theta] \rightarrow \mathbb{C}[z][q^{-\frac{1}{s}}][Q, \theta] \quad Q_Z^d \mapsto Q^{(\iota_Z)_* d} q^{-\frac{c_1(N_Z/W) \cdot d}{r-1}}.$$

We will now shift our variables in order to make our comparison. Let

$$\varsigma_j(\theta) = \sigma_j(\theta) - (r-1)\lambda_j.$$

Then

$$\widehat{\text{FT}}_{Z,j}^{\varsigma}: \widehat{\text{QDM}}_T(W) \rightarrow \varsigma_j^* \text{QDM}(Z)^{\text{ext,loc}}$$

intertwines the quantum connections up to a  $\frac{1}{2}$  shift in  $\mu_Z$ . Combining the Fourier transforms for the different fixed loci, we obtain

**Theorem 3.3.5** (Main theorem). *The diagram*

$$\begin{array}{ccc}
 & & \tau^* \mathrm{QDM}(X)^{\mathrm{ext}} \\
 & \nearrow \widehat{\mathrm{FT}}_X & \\
 \tilde{\tau}^* \mathrm{QDM}(\tilde{X})^{\mathrm{ext}} & \xrightarrow{\widehat{\mathrm{FT}}_X^{-1}} \widehat{\mathrm{QDM}}_T(W)_{\tilde{X}} & \\
 & \searrow \oplus_j \widehat{\mathrm{FT}}_{Z,j} & \\
 & & \oplus_j \zeta_j^* \mathrm{QDM}(Z)^{\mathrm{ext},\mathrm{loc}}
 \end{array}$$

*induces an isomorphism*

$$\tilde{\tau}^* \mathrm{QDM}(\tilde{X})^{\mathrm{ext}} \simeq \tau^* \mathrm{QDM}(X)^{\mathrm{ext}} \oplus \bigoplus_j \zeta_j^* \mathrm{QDM}(Z)^{\mathrm{ext},\mathrm{loc}}$$

*over  $\mathfrak{U}$  that intertwines the quantum connections and Poincaré pairings.*
